Energy at Hopkins

2 Stories

- Story 1 — The Broken Promise (New York Wind)
  - **2021:** New York awarded contracts for massive offshore wind farms (e.g., *Empire Wind 2*), meant to power millions of homes [1].
  - Contracts locked in, market signals clear, developers ready to build.
  - **By 2024:** plans collapsed — inflation, material bottlenecks, and shortages of submarine cables and turbines [2].
  - The contract was torn up: the market promised clean megawatts, but the supply chain couldn't deliver.

Supply chain — not contracts — dictated what was feasible.

2 Stories

- Story 2 — The Price Shock (PJM Capacity Market)
  - **2024:** PJM capacity auctions saw prices spike up to **800%** in some zones [3].
  - Consumers and businesses faced billions in extra costs.
  - **"We need new capacity, now!"**
  - Projects stalled in queues, with transformers, materials, and financing all in short supply.

Supply chain — not planning models — determined which projects could proceed.

[3] https://www.reuters.com/business/energy/pjm-power-auction-results-yield-sharply-higher-prices-2024-07-31
[4] https://opc-dc.gov/wp-content/uploads/2025/05/PJM-Capacity-Market-Report-FINAL-OPC-Synapse.pdf

Why? Mismatch between planning and supply chain reality!

- Historical Stability
  - Traditional assets (coal, gas, nuclear) relied on abundant, low-cost materials (steel, cement).
  - Supply costs were <5% of capex, even during price spikes [5]
  - Strong, guaranteed returns reinforced perception that upstream constraints weren't limiting [6].
  - Shift only recent: wind, solar, and storage depend on global, modular, supply-intensive chains.

- Data & Uncertainty
  - Downstream data (load, generation, prices) well-documented.
  - Upstream data (material availability, lead times) scarce & uncertain.
  - Lack of standardized datasets hinders formal modeling of supply chains.

- Modeling Gaps
  - Existing tools siloed: IAMs → global scale, coarse, long-term. LCAs → retrospective, static. Traditional GEP → ignores upstream.
  - No unified framework embedding supply dynamics into operationally relevant planning.

But, more than just megawatts..

Upstream Supply Chain Processes

Regulated capacity goals (exogenous).

?

- Planning is not only about exogenous capacity goals.
- It must also account for real operational constraints.

Integrating upstream supply chains into generation expansion planning [10]

[10] Yao, B., Bernstein, A., & Dvorkin, Y. (2025). Integrating Upstream Supply Chains into Generation Expansion Planning. arXiv preprint arXiv:2508.03001.

What is Capacity Expansion Planning

- **A long-term planning tool** decides what power plants, storage, and transmission to build, where, and when.
- **Balances trade-offs** among cost, reliability, and policy-driven goals under an uncertain future.
- **Integrates multiple time scales** i.e., short-term operations with long-term investment choices.
- **Informs policy and markets** by guiding regulators, utilities, and system operators on infrastructure and climate targets.

Integrating upstream supply chains into generation expansion planning [10]

- **Decisions (annual):** where/when/what to build or retire; product mix (e.g., SPV, LBW/OSW, BSS variants).
- **Operations (hourly, rep. days):** dispatch, storage charge/discharge, flows, load shedding.
- **Upstream layers:** materials → components → products mapped to capacity; lead time; stocks & recovery from retirements; field availability updates over time.

Objective = Investment + Operations + Penalties
Build new capacity, run the system, cover shortfalls.

Upstream layer:
1. Tracks materials → components → products.
2. Limits by production capacity & lead times.
3. Accounts for field availability.
4. Recovery from retired units.

Downstream layer:
1. **Balance**: generation + imports + storage = demand − shedding
2. **Limits**: generation, line capacity, load shedding bounds
3. **Evolution**: unit builds/retirements over years
4. **Battery:** charge/discharge ≤ rated capacity; SOC within bounds
5. **Reliability**: ELCC ≥ peak + reserves
6. **Compliance**: meet RPS targets (with slack)

From Model → Maryland

Maryland spatial and temporal representation

- 4 zones (BGE, APS, DPL, PEPCO) as nodes.
- Investments made annually; operations modeled hourly with 1 representative day per season (via k-means clustering).
- Transmission: 4-node network, PJM Window 3 upgrades assumed, no further expansion.
- Focus: captures supply chain impacts in long-term planning.

Assumptions

- Resources: existing + new (renewables, batteries only) (per MD regs & queue).
- Lifetimes: retire at design end (+1 year if exceeded).
- Materials: 14 critical materials → 12 key products.
- Supply: domestic, imports, stock, 10% recycling.
- Lead times: fixed tech-specific delays.
- Field: land & offshore limits; shared zones; reuse after retirements.

Scenarios:

- **Low**: excludes aggressive electrification & data center growth.
- **High**: includes both electrification & data center growth.
- Sub-Scenarios:
  - **w/o SC** (relaxed): unlimited materials, no lead times, expanded land/offshore areas.
  - **lim. SC** (constrained): materials limited to domestic + allied sources, with lead times & land limits reflecting geopolitical/trade risks

From Model → Maryland

- **Baseline**

From Model → Maryland

- **w/o SC** (relaxed): unlimited materials, no lead times, expanded land/offshore areas.

From Model → Maryland

- **lim. SC (constrained):** materials limited to domestic + allied sources, with lead times & land limits reflecting geopolitical/trade risks

From Model → Maryland

Operational capacity over time for baseline Low and High scenarios. Stacked bars: tech-specific capacity (Low baseline = left); Lines: net peak load (system demand)

- Low baseline (2053): 4.1 GW BSS, 1.5 GW LBW, 1.4 GW OSW, 8.5 GW SPV → more diversified mix.
- High baseline (2053): 7.3 GW BSS, 0.5 GW LBW, 0.4 GW OSW, 19.5 GW SPV → solar-dominant growth.

Optimization Results for Status Variables: (a) Planning Capacity, (b) Built Capacity.

From Model → Maryland

Planned product by technology (top) and remaining material availability (bottom) for baseline Low and High scenarios.

- Low baseline:
  - Pre-2031: SPV/BSS constrained by silicon & nickel bottlenecks.
  - 2040s: shift to LBW & OSW as costs fall and materials accumulate.
  - Mix of gearbox & direct-drive OSW to balance nickel vs. neodymium use.
- High baseline:
  - Continuous load growth → sustained SPV build to 2046 (fast build, low material use).
  - Storage shifts from NMC 111 (cobalt) to NMC 811 (nickel).
  - 2047: SPV insufficient → add LBW & OSW (direct-drive favored for nickel limits).

From Model → Maryland

Field availability at the beginning of each year: land (top) and offshore (bottom) area for new deployment.

- Post-2049: land outside BGE fully allocated → spatial constraint binds
- Response: shift to BSS (low land need, short lead time)
- Materials: move toward NMC 811 (less cobalt) while keeping some NMC 111 for balance

Scenario Comparisons

Without supply chain constraints, plans build only when needed.

Difference in planned capacity by technology between the w/o SC and baseline. Positive values indicate technologies favored in w/o SC.

- **w/o SC (relaxed):**
  - Unlimited materials & no lead times → just-in-time planning.
  - Low: LBW added in 2048 (cheap & land available).
  - High: sustained load growth → more OSW after 2045.

Scenario Comparisons

Difference in planned product deployment between the lim. SC and baseline. Positive values indicate technologies favored in lim. SC.

- c-Si preferred → strong domestic supply
- NMC-811 not preferred → nickel import dependence

- **lim. SC (constrained):**
  - Critical material limits (esp. rare earths) → no new wind after 2045.
  - SPV (c-Si) favored due to steady silicon supply.
  - BSS shift: NMC 811 → NMC 111 (less nickel).
  - Stronger shift in High case due to higher load stress.

Scenario Comparisons

Yearly load shedding and reserve margin shortfalls across all scenarios.

- **Reliability:**
  - w/o SC: almost no issues (flexible, fast build).
  - baseline: early shortfalls (2025 retirements), mostly resolved by 2041.
  - lim. SC: persistent reserve margin violations; load shedding in High from 2037 onward; major gap after 2048 NGCC retirements remains unresolved.

Key Takeaways

- Ignoring supply chains underestimates costs and reliability risks.
- Low vs. High: modest cost increase in Low; severe shortfalls and load shedding in High.
- Just-in-time planning is infeasible — requires earlier, strategic investments and possible lifetime extensions.
- Constraints can overturn cost advantages — diversification across technologies is critical.
- Anticipatory planning needed to avoid over-correction and material exhaustion.
